

2-Methoxyestradiol

Catalog No: tcsc0176

Available Sizes

Size: 10mg

Size: 50mg

Size: 100mg

Specifications

CAS No:

362-07-2

Formula:

$C_{19}H_{26}O_3$

Pathway:

Cell Cycle/DNA Damage;Cytoskeleton;Apoptosis

Target:

Microtubule/Tubulin;Microtubule/Tubulin;Apoptosis

Purity / Grade:

>98%

Solubility:

H₂O :

Alternative Names:

2-ME2;NSC-659853

Observed Molecular Weight:

302.41

Product Description

2-Methoxyestradiol is an **angiogenesis** inhibitor and **apoptosis** inducer with potent antineoplastic activity. 2-Methoxyestradiol also destabilize **microtubules**.

IC50 & Target: IC50: 1.2 μ M (tubulin/microtubule, in living interphase MCF7 cells)^[1]

In Vitro: 2-Methoxyestradiol (5-100 μ M) inhibits assembly of purified tubulin in a concentration-dependent manner, with maximal inhibition (60%) at 200 μ M 2-Methoxyestradiol (2ME2). However, with microtubule-associated protein-containing microtubules, significantly higher 2-Methoxyestradiol concentrations are required to depolymerize microtubules, and polymer mass is reduced by only 13% at 500 μ M 2-Methoxyestradiol. 4 μ M 2-Methoxyestradiol reduces the mean growth rate by 17% and dynamicity by 27%. In living interphase MCF7 cells at the IC₅₀ for mitotic arrest (1.2 μ M), 2-Methoxyestradiol significantly suppresses the mean microtubule growth rate, duration and length, and the overall dynamicity, consistent with its effects in vitro, and without any observable depolymerization of microtubules. 2-Methoxyestradiol induces G₂-M arrest and apoptosis in many actively dividing cell types while sparing quiescent cells. 2-Methoxyestradiol binds to tubulin at or near the colchicine site, it inhibits microtubule assembly, and high concentrations have been shown to depolymerize microtubules in cells. 2-Methoxyestradiol induces G₂-M arrest and apoptosis in many actively dividing also blocks mitosis and inhibits endothelial cell migration^[1]. 2-Methoxyestradiol (2-ME) decreases the HIF-1 α and HIF-2 α nuclear staining in cells cultured under hypoxia. The HIF-1 α and HIF-2 α mRNA levels are significantly lower when cells are exposed to 2-Methoxyestradiol under normoxia and hypoxia. 2-Methoxyestradiol is an anti-angiogenic, anti-proliferative and pro-apoptotic agent that suppresses HIF-1 α protein levels and its transcriptional activity. A significant decrease in the growth rate is found in the 10 μ M 2-Methoxyestradiol-treated A549 cells in comparison with the DMSO-treated cells (66.2 \pm 7.2 and 101.2 \pm 2.3%, respectively; p=0.04) at 96 h. 2-Methoxyestradiol at a concentration of 10 μ M is used for the apoptosis and HIF-1 α and HIF-2 α expression assays, due to the significance found for this concentration when cells are incubated under normoxic conditions at 72 h. A significant increase in apoptosis is observed in cells treated with 10 μ M 2-Methoxyestradiol in a normoxic condition in comparison with cells under lower O₂ concentration (5.8 \pm 0.2%; p=0.003)^[2].

In Vivo: To investigate the effect of 2ME2 on uveitis development, C57BL/6 mice are randomly assigned into two groups and immunized with IRBP peptide. 2ME2 group starts 2-Methoxyestradiol (15 mg/kg) intraperitoneally from day 0 to day 13 while control group is given with vehicle. The disease score of 2-Methoxyestradiol (2ME2) group is 0.30 \pm 0.30, significantly lower than that of control group 2.09 \pm 0.28 (p[3]. Treatment with 2-Methoxyestradiol (60-600 mg/kg/d) results in a dose-dependent inhibition of tumor growth. The percentage of cells with strong pimonidazole-positive staining (+++) is significantly decreased in the 2-Methoxyestradiol-treated group (36.0% for 60 mg/kg/d and 0% for 200 and 600 mg/kg/d) compare with the vehicle-treated group (86.5%). This may be attributed to the dramatic inhibition of tumor growth in a dose-dependent manner following 2-Methoxyestradiol treatment^[4].
